**PRODUCT INFORMATION**
**FEMOSTON®-CONTI TABLETS**

**WARNING**
Estrogens and progestogens should not be used for the prevention of cardiovascular disease or dementia.

The Women’s Health Initiative (WHI) study reported increased risks of myocardial infarction, stroke, invasive breast cancer, pulmonary emboli, and deep vein thrombosis in postmenopausal women (50 to 79 years of age) during 5 years of treatment with conjugated estrogens (0.625 mg) combined with medroxyprogesterone acetate (2.5 mg) relative to placebo (see ‘CLINICAL TRIALS’ and ‘PRECAUTIONS’).

The WHI study reported increased risks of stroke and deep vein thrombosis in postmenopausal women (50 to 79 years of age) during 6.8 years of treatment with conjugated estrogens (0.625 mg) relative to placebo (see ‘CLINICAL TRIALS’ and ‘PRECAUTIONS’).

The Women’s Health Initiative Memory Study (WHIMS), a sub-study of WHI, reported increased risk of developing probable dementia in postmenopausal women 65 years of age or older during 4 to 5.2 years of treatment with conjugated estrogens, with or without medroxyprogesterone acetate, relative to placebo. It is unknown whether this finding applies to younger postmenopausal women (see ‘CLINICAL TRIALS’ and ‘PRECAUTIONS’).

Other doses of conjugated estrogens and medroxyprogesterone acetate, and other combinations and dosage forms of estrogens and progestogens were not studied in the WHI clinical trials and, in the absence of comparable data, these risks should be assumed to be similar. Because of these risks, estrogens with or without progestogens should be prescribed at the lowest effective doses and for the shortest duration consistent with treatment goals and risks for the individual woman.

**NAME OF THE MEDICINE**

**Non-proprietary Name**
Estradiol and Dydrogesterone

**Chemical Structure**
Estradiol

Chemical Name: Estra-1,3,5(10)-triene-3, 17β-diol.

![Chemical Structure Diagram](image)

C_{18}H_{24}O_{2}, MW: 272.4
Dydrogesterone
Chemical Name: 9β, 10α-pregna-4, 6 diene-3, 20 dione.

C_{21}H_{29}O_{2}, MW: 312.5

CAS Number
Estradiol: 50-28-2 (anhydrous)
Dydrogesterone: 152-62-5

DESCRIPTION
Estradiol
It is a white, or creamy-white, odourless, hygroscopic crystals or crystalline powder. Melting point: approximately 175°C to 180°C. Solubility: Practically insoluble in water; slightly soluble in alcohol and in fixed oils; sparingly soluble in acetone.

Dydrogesterone
It is a white to pale yellow crystalline powder; odourless to almost odourless. Melting point: approximately 167°C to 171°C. Solubility: Practically insoluble in water; freely soluble in chloroform; soluble in acetone; slightly soluble in ethanol (96%) and in methanol; and slightly in ether and in fixed oils;

Femoston-Conti tablets are immediate-release, film-coated tablets for oral use containing 1 mg estradiol and 5 mg dydrogesterone. Femoston-Conti tablets also contain the excipients; lactose monohydrate, hypromellose, maize starch, colloidal anhydrous silica, magnesium stearate and Opadry OY-8734 orange.

PHARMACOLOGY
Pharmacodynamics
The estrogenic agent, estradiol, is chemically and biologically identical to endogenous human estradiol and has pharmacological actions similar to the physiological effects of the endogenous hormone. Estradiol is the primary estrogen and the most active of the ovarian hormones. The Femoston-Conti estradiol preparation relieves the vasomotor symptoms arising from the decrease in the ovarian estrogen production, resulting from natural or artificially induced menopause. In addition to relieving or eliminating these symptoms, estrogen replacement therapy has also been demonstrated to retard or halt postmenopausal bone mass loss (osteoporosis) and to play an important role in fat metabolism.

Dydrogesterone given orally has progestational effects similar to parenterally administered progesterone. Unopposed estrogen treatment has been reported to increase the risk of endometrial carcinoma. The inclusion of dydrogesterone induces a secretory endometrium in an estrogen-primed uterus. Dydrogesterone does not cause androgenic side effects.
In the context of continuous combined HRT, dydrogesterone produces an atrophic endometrium and amenorrhoea, thereby providing protection against estrogen-induced increased risk of endometrial hyperplasia and/or carcinoma.

**Pharmacokinetics**

Micronised estradiol is rapidly and efficiently absorbed from the gastrointestinal tract. Following oral administration, estradiol is extensively metabolised. The major unconjugated and conjugated metabolites are estrone and estrone sulfate. These metabolites may contribute to the estrogenic activity, either directly or following conversion to estradiol. Conjugates of the various estrogens and their metabolites are excreted in the urine, whilst unconjugated metabolites appear in the faeces. Estrogens are also secreted in the milk of nursing mothers.

Following oral administration, dydrogesterone is completely metabolised, with an average 63% of the dose excreted into the urine. Excretion is complete within 72 hours. The major metabolite of dydrogesterone is 20α-dihydrodydrogesterone (DHD), excreted predominantly in the urine as the glucuronic acid conjugate. A common feature of all metabolites of dydrogesterone characterised is the retention of the 4,6 diene-3-one configuration of the parent compound and the absence of 17α-hydroxylation. This accounts for the lack of estrogenic and androgenic effects of dydrogesterone. Plasma concentrations of DHD following oral administration of dydrogesterone are substantially higher in comparison to the parent drug. The AUC and Cmax ratios of DHD to dydrogesterone are in the order of 40 and 25, respectively. The Tmax values of dydrogesterone and DHD vary between 0.5 and 2.5 hours. The mean terminal half-lives of dydrogesterone and DHD vary between 5 to 7 and 14 to 17 hours, respectively. Unlike progesterone, dydrogesterone is not excreted in urine as pregnanediol. It therefore remains possible to analyse endogenous progesterone production based on pregnanediol excretion. No clinically relevant pharmacokinetic interactions occur between estradiol and dydrogesterone.

**CLINICAL TRIALS**

The efficacy of estradiol in relieving menopausal symptoms was demonstrated in a one year, double-blind, randomised study, using 1 mg estradiol continuously combined with 5 mg to 20 mg dydrogesterone (n=318), and in a one year open label study investigating the effects of 1 mg estradiol continuously combined with 2.5 mg dydrogesterone (n=165). In both studies, relief of menopausal symptoms was a secondary outcome. In comparison with baseline, a considerable decrease in frequency of hot flushes was observed, with majority of the effect noted by the first observation point at 6 weeks and the effect maintained to the end of the study. Both studies also demonstrated a decrease in frequency of night sweats, sweating attacks and sleeplessness. The dose and duration of dydrogesterone had no influence on the efficacy of estradiol in relieving menopausal symptoms.

Endometrial protection was evaluated in studies involving 1103 postmenopausal women. Protection against endometrial stimulation was investigated in two studies (n = 310) using 2mg estradiol combined with 2.5, 5, 10 and 15 mg dydrogesterone. Adequacy of the progesterational response (absence of endometrial hyperplasia) after 6 months treatment was determined to be greater than 99% for all doses of dydrogesterone tested. A proliferative endometrium was reported in 7% of women, the majority being on 2.5 mg dydrogesterone. Protection against endometrial stimulation was also investigated in 3 studies using 1 mg estradiol continuously combined with 2.5, 5, 10 and 20 mg dydrogesterone (n = 650). As with the 2 mg estradiol dose the adequacy of the progestational response (absence of endometrial hyperplasia) after 12 months treatment was determined to be greater than 99% for all doses of dydrogesterone tested. Endometrial proliferation was reported in 3% of women, majority being on 2.5 mg dydrogesterone. The dose selected to oppose 1 mg estradiol in a continuous combined
regimen was therefore 5 mg, which was associated with a hyperplasia rate of 0.6% and a proliferation rate of 2%.

Data from a study on postmenopausal women (n=214), who had not received HRT previously, in which 1 mg estradiol was combined daily with either 5, 10 or 20 mg dydrogesterone, showed a statistically significant (p<0.001) increase in bone mineral density (BMD) at the lumbar spine (3.6%) and femoral neck (1.2%) after one year. Irregular bleeding was reduced by about 50% on 1 mg estradiol, amenorrhea rates doubled at 6 months and early withdrawals due to vaginal bleeding were halved. By one year, over 80% of women on 1 mg estradiol were amenorrhoic.

**Bone Mineral Density Effects**

In a two-year, double-blind, placebo controlled study in postmenopausal women the effects of 1 mg and 2 mg estradiol sequentially combined with 5-20 mg dydrogesterone was investigated. A clinically relevant and statistically significant (p<0.001) mean increase in BMD was observed in the lumbar spine and femoral neck after 1 and 2 years, in both the 1 mg and 2 mg groups of the evaluable patient sample (n=409). At 2 years, the mean increases in BMD at the femoral neck were 2.7% (+4.24) with 1 mg estradiol and 2.5% (+4.99) with 2 mg estradiol, and the increase in the lumbar spine was 5.2% (+3.76) with 1 mg estradiol and 6.7% (+3.83) with 2 mg estradiol. Both increases were statistically significant from baseline, but not from each other.

**Lipid Effects**

A one-year double-blind study in postmenopausal women (n=304) investigated the effects of 1 mg estradiol combined with daily dydrogesterone 5-20 mg on serum lipids. In all groups, over 52 weeks, HDL levels increased (+5%), LDL and total cholesterol levels both decreased (-9% and -6% respectively), and lipoprotein(a) levels also decreased (-12.5%). There were no significant differences between the three dosages. The favourable changes in lipid profiles seen with sequential Femoston are also seen with Femoston-Conti.

As reported in observational studies, an improvement of the lipid profile may be a factor contributing to the beneficial effect of estrogens in reducing the risk of coronary heart disease in postmenopausal women. However, the long-term effects of these changes on the cardiovascular system are unknown.

**Women’s Health Initiative Studies**

A sub-study of the Women’s Health Initiative (WHI) enrolled 16,608 predominantly healthy postmenopausal women (average age of 63 years, range 50 to 79; 83.9% White, 6.5% Black, 5.5% Hispanic) to assess the risks and benefits of the use of a continuous combined regimen of conjugated estrogens (CE) 0.625 mg plus medroxyprogesterone acetate (MPA) 2.5 mg per day compared to placebo in the prevention of certain chronic diseases. The primary endpoint was the incidence of coronary heart disease (CHD) (nonfatal myocardial infarction and CHD death), with invasive breast cancer as the primary adverse outcome studied. A “global index” included the earliest occurrence of CHD, invasive breast cancer, stroke, pulmonary embolism (PE), endometrial cancer, colorectal cancer, hip fracture, or death due to other cause. The study did not evaluate the effects of CE plus MPA on menopausal symptoms. The estrogen plus progestogen sub-study was stopped early because, according to the predefined stopping rule, the increased risk of breast cancer and cardiovascular events exceeded the specified benefits included in the “global index.” Results are presented in Table 1 below:

<table>

</table>

For those outcomes included in the “global index”, the absolute excess risks per 10,000 women-years in the group treated with CE + MPA were 7 more CHD events, 8 more strokes, 8 more PEs, and 8 more invasive breast cancers, while the absolute risk reductions per 10,000 women-years were 6 fewer colorectal cancers and 5 fewer hip fractures. The absolute excess risk of events included in the “global index” was 19 per 10,000 women-years. There was no difference between the groups in terms of all-cause mortality (see ‘Boxed Warning’ and ‘PRECAUTIONS’).

**Women’s Health Initiative Memory Study**

The Women’s Health Initiative Memory Study (WHIMS), a sub-study of WHI, enrolled 4,532 predominantly healthy postmenopausal women 65 years of age and older (47% were age 65 to 69 years, 35% were 70 to 74 years, and 18% were 75 years of age and older) to evaluate the effects of CE plus MPA on the incidence of probable dementia (primary outcome) compared with placebo.

After an average follow-up of 4 years, 40 women in the estrogen/progestogen group (45 per 10,000 women-years) and 21 in the placebo group (22 per 10,000 women-years) were diagnosed with probable dementia. The relative risk of probable dementia in the hormone therapy group was 2.05 (95% CI, 1.21 to 3.48) compared to placebo. Differences between groups became apparent in the first year of treatment. It is unknown whether these findings apply to younger postmenopausal women. (see ‘Boxed Warning’ and ‘PRECAUTIONS – Dementia and Use in the Elderly’).

---

a: adapted from JAMA, 2002; 288:321-333

b: includes metastatic and non-metastatic breast cancer with the exception of in situ breast cancer
c: a subset of the events was combined in a “global index”, defined as the earliest occurrence of CHD events, invasive breast cancer, stroke, pulmonary embolism, endometrial cancer, colorectal cancer, hip fracture, or death due to other causes
d: not included in Global Index

*: nominal confidence intervals unadjusted for multiple looks and multiple comparisons. Except for deep vein thrombosis and other osteoporotic fractures, based on adjusted confidence intervals, the relative risks were not statistically significant.
INDICATIONS
Hormone replacement therapy (HRT) in estrogen deficiency associated with natural or artificial menopause in women with an intact uterus. Prevention of postmenopausal bone mineral density loss in women.

For initiation and continuation of treatment of postmenopausal symptoms, the lowest effective dose for the shortest duration should be used with the goal being short term use. (see ‘DOSAGE AND ADMINISTRATION’ and ‘CLINICAL TRIALS’).

When prescribed solely for the prevention of postmenopausal bone mineral density loss, therapy should only be prescribed for women who are at high risk of osteoporosis and future fracture and who are intolerant of, or contraindicated for non-estrogen products approved for prevention of osteoporosis. Life style modifications and the risk benefit profile of Femoston-Conti should be taken into careful consideration and discussed with the patient, to allow the patient to make an informed decision prior to prescribing (see ‘PRECAUTIONS’ and ‘DOSAGE AND ADMINISTRATION’).

CONTRAINDICATIONS
- Women who have had a hysterectomy
- Known or suspected carcinoma of the breast, endometrium or other estrogen dependent neoplasia
- Known or suspected progestogen dependent neoplasms
- Untreated endometrial hyperplasia
- Active or chronic liver disease or a history of liver disease where the liver function tests have failed to return to normal
- Cerebrovascular accident or a past history of the condition associated with previous estrogen use
- Previous idiopathic or current venous thromboembolism (deep venous thrombosis, pulmonary embolism) or cerebrovascular accident
- Known thrombophilic disorders (e.g. protein C, protein S or antithrombin deficiency, see ‘PRECAUTIONS’)
- Active or recent arterial thromboembolic disease (e.g. angina, myocardial infarction)
- Abnormal genitourinary tract bleeding of unknown aetiology
- Porphyria
- Known or suspected pregnancy
- Lactation
- Known hypersensitivity to any ingredients contained in Femoston-Conti tablets

PRECAUTIONS
The benefits and risks of estrogen/progestogen therapy must always be carefully weighed including consideration of the emergence of risks as therapy continues.

Medical Examination/ Follow up
Before initiating therapy, a complete medical and family history should be taken and a physical examination performed. Pre-treatment and subsequent physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs. Mammography is advisable. Patients who are being, or have previously been treated with unopposed estrogens should be examined with special care to exclude endometrial stimulation before commencing Femoston-Conti therapy.
As a general rule, hormone replacement therapy (HRT) should not be prescribed for longer than one year without another physical examination including gynaecological examination being performed. Women on HRT should have regular breast examinations, and regular mammography (every 1-2 years). In all cases of undiagnosed, persistent or recurring abnormal vaginal bleeding, adequate diagnostic measures, including endometrial sampling, should be undertaken to rule out malignancy. The benefits and risks of HRT should be carefully considered. HRT should be dosed at the lowest effective dose to relieve symptoms and for the shortest duration for control of symptoms.

**Cardiovascular Disorders**

Estrogen/progestogen therapy has been associated with an increased risk of cardiovascular events such as myocardial infarction and stroke, as well as venous thrombosis and pulmonary embolism (venous thromboembolism or VTE). Should any of these occur or be suspected, estrogen/progestogen therapy should be discontinued immediately.

Risk factors for arterial vascular disease (e.g., hypertension, diabetes mellitus, tobacco use, hypercholesterolaemia, and obesity) and/or venous thromboembolism (e.g., personal history or family history of VTE, obesity, and systemic lupus erythematosus) should be managed appropriately.

**Coronary Heart Disease and Stroke**

In the estrogen plus progestogen sub-study of the Women’s Health Initiative (WHI) study, an increased risk of coronary heart disease (CHD) events (defined as nonfatal myocardial infarction and CHD death) was observed in women receiving CE plus MPA compared to women receiving placebo (37 vs 30 per 10,000 women-years). The increase in risk was observed in year one and persisted (see ‘CLINICAL TRIALS’).

In the same sub-study of WHI, an increased risk of stroke was observed in women receiving estrogen plus progestogen compared to women receiving placebo (29 vs 21 per 10,000 women-years). The increase in risk was observed after the first year and persisted. The relative risk does not change with age or time since menopause. However, as the baseline risk of stroke is strongly age-dependent, the overall risk of stroke in women who use HRT will increase with age (see ‘ADVERSE EFFECTS’).

In postmenopausal women with documented heart disease (n = 2,763, average age 66.7 years) a controlled clinical trial of secondary prevention of cardiovascular disease (Heart and Estrogen/progestin Replacement Study; HERS) treatment with CE plus MPA demonstrated no cardiovascular benefit. During an average follow-up of 4.1 years, treatment with CE plus MPA did not reduce the overall rate of CHD events in postmenopausal women with established coronary heart disease. There were more CHD events in the estrogen/progestogen-treated group than in the placebo group in year 1, but not during the subsequent years. Two thousand three hundred and twenty-one women from the original HERS trial agreed to participate in an open label extension of HERS, HERS II. Average follow-up in HERS II was an additional 2.7 years, for a total of 6.8 years overall. Rates of CHD events were comparable among women in the estrogen/progestogen-treated group and the placebo group in HERS, HERS II, and overall.

**Venous Thromboembolism (VTE)**

In the estrogen plus progestogen sub-study of WHI, a 2-fold greater rate of VTE, including deep venous thrombosis and pulmonary embolism, was observed in women receiving CE + MPA compared to women receiving placebo. The rate of VTE was 34 per 10,000 women-years in the estrogen plus progestogen-treated group compared to 16 per 10,000 women-years in the placebo group. The increase in VTE risk was observed during the first year and persisted (see ‘CLINICAL TRIALS’).
Patients with known thrombophilic states have an increased risk of VTE and HRT may add to this risk. HRT is therefore contraindicated in these patients (see ‘CONTRAINICATIONS’).

Generally recognised risk factors for VTE include: use of estrogens, older age, major surgery, prolonged immobilisation, obesity (BMI > 30 kg/m²), pregnancy/postpartum period, systemic lupus erythematosus (SLE), and cancer. There is no consensus about the possible role of varicose veins in VTE.

As in all postoperative patients, prophylactic measures need to be considered to prevent VTE following surgery. If feasible, estrogens should be discontinued at least 4 to 6 weeks before surgery of the type associated with an increased risk of thromboembolism, or during periods of prolonged immobilisation. Treatment should not be restarted until the woman is completely mobilised.

In women with no personal history of VTE but with a close relative with a history of thrombosis at a young age, screening may be offered after careful counselling regarding its limitations (only a proportion of thrombophilic defects are identified by screening).

If a thrombophilic defect is identified which segregates with thrombosis in family members or if the defect is 'severe' (e.g. antithrombin, protein S, or protein C deficiencies or a combination of defects) HRT is contraindicated.

Women already on chronic anticoagulant treatment require careful consideration of the benefit-risk of use of HRT.

If VTE develops after initiating therapy, the drug should be discontinued. Patients should be told to contact their doctor immediately they are aware of a potential thromboembolic-symptom (e.g. painful swelling of a leg, sudden pain in the chest, dyspnoea).

**Malignant Neoplasms**

**Breast cancer**

The use of estrogens and progestogens by postmenopausal women has been reported to increase the risk of breast cancer. The most important randomised clinical trial providing information about this issue is the Women's Health Initiative (WHI) trial of estrogen plus progestogen (see ‘CLINICAL TRIALS’). The results from observational studies are generally consistent with those of the WHI clinical trial.

After a mean follow-up of 5.6 years, the WHI trial reported an increased risk of breast cancer in women who took estrogen plus progestogen. Observational studies have also reported an increased risk for estrogen/progestogen combination therapy, and a smaller increased risk for estrogen alone therapy, after several years of use. For both findings, the excess risk increased with duration of use, and appeared to return to baseline over about five years after stopping treatment (only the observational studies have substantial data on risk after stopping). In these studies, the risk of breast cancer was greater, and became apparent earlier, with estrogen/progestogen combination therapy as compared to estrogen alone therapy. However, these studies have not found significant variation in the risk of breast cancer among different estrogens or among different estrogen/progestogen combinations, doses, or routes of administration.

In the WHI trial of estrogen plus progestogen, 26% of the women reported prior use of estrogen alone and/or estrogen/progestogen combination hormone therapy. After a mean follow-up of 5.6 years during the clinical trial, the overall relative risk of invasive breast cancer was 1.24 (95% confidence interval 1.01-1.54), and the overall absolute risk was 41 vs. 33 cases per 10,000 women-years, for estrogen plus progestogen compared with placebo. Among women who reported prior use of hormone therapy, the relative risk of invasive breast cancer was 1.86, and the absolute risk was 46 vs. 25 cases per 10,000 women-years, for estrogen plus progestogen compared with placebo. Among women who reported no prior use of hormone therapy, the relative risk of invasive breast cancer was 1.09, and the absolute risk was 40 vs. 36 cases per 10,000 women-years for estrogen plus progestogen compared with placebo. In the WHI trial, invasive breast
cancers were larger and diagnosed at a more advanced stage in the estrogen plus progestogen group compared with the placebo group. Metastatic disease was rare with no apparent difference between the two groups. Other prognostic factors such as histologic subtype, grade and hormone receptor status did not differ between the groups.

The observational Million Women Study in Europe reported an increased risk of mortality due to breast cancer among current users of estrogens alone or estrogens plus progestogens compared to never users, while the estrogen plus progestogen sub-study of WHI showed no effect on breast cancer mortality with a mean follow-up of 5.6 years.

The use of estrogen plus progestogen has been reported to result in an increase in abnormal mammograms requiring further evaluation. All women should receive yearly breast examinations by a healthcare provider and perform monthly breast self-examinations. In addition, mammography examinations should be scheduled based on patient age, risk factors, and prior mammogram results.

HRT, especially estrogen-progestogen combined treatment, increases the density of mammographic images which may adversely affect the radiological detection of breast cancer.

**Endometrial cancer**

The reported endometrial cancer risk among unopposed estrogen users is about 2- to 12-fold greater than in nonusers, and appears dependent on duration of treatment and on estrogen dose. Most studies show no significant increased risk associated with the use of estrogens for less than one year. The greatest risk appears associated with prolonged use, with increased risks of 15- to 24-fold for five to ten years or more, and this risk has been shown to persist for at least 8 to 15 years after estrogen therapy is discontinued.

**Addition of a progestogen when a woman has not had a hysterectomy**

Studies of the addition of a progestogen for 10 or more days of a cycle of estrogen administration, or daily with estrogen in a continuous regimen, have reported a lowered incidence of endometrial hyperplasia than would be induced by estrogen treatment alone. Endometrial hyperplasia may be a precursor to endometrial cancer. There are, however, possible risks that may be associated with the use of progestogens with estrogens compared with estrogen-alone regimens. These include a possible increased risk of breast cancer, adverse effects on lipoprotein metabolism (e.g. lowering HDL, raising LDL) and impairment of glucose tolerance. Clinical surveillance of all women taking estrogen/progestogen combinations is important. Adequate diagnostic measures, including endometrial sampling when indicated, should be undertaken to rule out malignancy in all cases of undiagnosed persistent or recurring abnormal vaginal bleeding. There is no evidence that the use of natural estrogens results in a different endometrial risk profile than synthetic estrogens of equivalent estrogen dose.

**Dementia**

In the Women’s Health Initiative Memory Study (WHIMS), an ancillary study of WHI, a population of 4,532 women aged 65 to 79 years was randomised to CE plus MPA or placebo. A population of 2,947 hysterectomised women, aged 65 to 79 years, was randomised to CE alone or placebo. In the planned analysis, pooling the events in women receiving CE alone or CE plus MPA in comparison to those in women on placebo, the overall relative risk (RR) for probable dementia was 1.76 (95% CI 1.19-2.60). In the estrogen-alone group, after an average follow-up of 5.2 years a RR of 1.49 (95% CI 0.83-2.66) for probable dementia was observed compared to placebo. In the estrogen-plus-progestogen group, after an average follow-up of 4 years, a RR of 2.05 (95% CI 1.21-3.48) for probable dementia was observed compared to placebo. Since this study was conducted in women aged 65 to 79 years, it is unknown whether these findings apply to younger postmenopausal women (see ‘PRECAUTIONS’ and ‘Use in the Elderly’).
Gallbladder Disease
A 2- to 4-fold increase in the risk of gallbladder disease requiring surgery in postmenopausal women receiving estrogens has been reported.

Hypercalcaemia
Estrogen administration may lead to severe hypercalcaemia in patients with breast cancer and bone metastases. If hypercalcaemia occurs, use of the drug should be stopped and appropriate measures taken to reduce the serum calcium level.

Visual Abnormalities
Retinal vascular thrombosis has been reported in patients receiving estrogens. Discontinue medication pending examination if there is sudden partial or complete loss of vision, or a sudden onset of proptosis, diplopia, or migraine. If examination reveals papilloedema or retinal vascular lesions, estrogens should be discontinued.

Elevated Blood Pressure
In a small number of case reports, substantial increases in blood pressure have been attributed to idiosyncratic reactions to estrogens. In a large, randomised, placebo-controlled clinical trial, a generalised effect of estrogen therapy on blood pressure was not seen. Blood pressure should be monitored at regular intervals with estrogen use.

Hypertriglyceridaemia
In patients with pre-existing hypertriglyceridaemia, estrogen therapy may be associated with elevations of plasma triglycerides leading to pancreatitis and other complications.

Impaired Liver Function and Past History of Cholestatic Jaundice
Estrogens may be poorly metabolised in patients with impaired liver function. For patients with a history of cholestatic jaundice associated with past estrogen use or with pregnancy, caution should be exercised and in the case of recurrence, medication should be discontinued.

Hypothyroidism
Estrogen administration leads to increased thyroid-binding globulin (TBG) levels. Patients with normal thyroid function can compensate for the increased TBG by making more thyroid hormone, thus maintaining free T4 and T3 serum concentrations in the normal range. Patients dependent on thyroid hormone replacement therapy who are also receiving estrogens may require increased doses of their thyroid replacement therapy. These patients should have their thyroid function monitored in order to maintain their free thyroid hormone levels in an acceptable range.

Fluid Retention
Because estrogens/progestogens may cause some degree of fluid retention, patients with conditions that might be influenced by this factor, such as cardiac or renal dysfunction, warrant careful observation when estrogens are prescribed.

Hypocalcaemia
Estrogens should be used with caution in individuals with severe hypocalcaemia.

Ovarian Cancer
Ovarian cancer is much rarer than breast cancer. Epidemiological evidence from a large meta-analysis suggests a slightly increased risk in women taking estrogen-only or combined estrogen-progestogen HRT, which becomes apparent within 5 years of use and diminishes over time after stopping. Some other studies, including the WHI trial suggest that use of combined HRTs may be associated with a similar, or slightly smaller risk (see ‘ADVERSE EFFECTS’).
Exacerbation of Endometriosis
Endometriosis may be exacerbated with administration of estrogen therapy.

Exacerbation of other Conditions
Estrogen therapy may cause an exacerbation of asthma, diabetes mellitus, epilepsy, migraine, porphyria, systemic lupus erythematosus, and hepatic haemangiomas and should be used with caution in women with these conditions.

Conditions which need supervision
If any of the following conditions are present, have occurred previously, and/or have been aggravated during pregnancy or previous hormone treatment, the patient should be closely supervised. It should be taken into account that these conditions may recur or be aggravated during treatment with Femoston-Conti, in particular:

- Leiomyoma (uterine fibroids) or endometriosis
- Risk factors for thromboembolic disorders
- Risk factors for estrogen dependent tumours e.g. 1st degree heredity for breast cancer
- Hypertension
- Liver disorders (e.g. liver adenoma)
- Diabetes mellitus with or without vascular involvement
- Cholelithiasis
- Migraine or (severe) headache
- Systemic lupus erythematosus
- A history of endometrial hyperplasia
- Epilepsy
- Asthma
- Otosclerosis

Reasons for immediate withdrawal of therapy
Therapy should be discontinued in case a contraindication is discovered and in the following situations:

- Jaundice or deterioration in liver function
- Significant increase in blood pressure
- New onset of migraine-type headache, sudden partial or complete loss of vision, sudden onset of proptosis.
- Pregnancy

Bleeding Patterns
Breakthrough bleeding and spotting may occasionally occur during the first months of treatment. If breakthrough bleeding or spotting appears after some time on therapy, or continues after treatment has been discontinued, the reason should be investigated, which may include endometrial biopsy to exclude endometrial malignancy.

Other conditions
Estrogens may cause fluid retention, and therefore patients with cardiac or renal dysfunction should be carefully observed. Patients with terminal renal insufficiency should be closely observed, since it is expected that the level of circulating active ingredients in Femoston-Conti is increased.
Published literature has reported an increased risk of inflammatory bowel disease (ulcerative colitis and Crohn's disease) in association with HRT use.

Estrogens and progestogens (C19) can influence carbohydrate metabolism. This has not been observed with hormone replacement therapy involving natural estrogens.

Patients with rare hereditary problems of galactose intolerance, the Lapp lactase deficiency or glucose-galactose malabsorption should not take this medicine.

Femoston-Conti is not an oral contraceptive. Patients in the perimenopausal phase should be advised to use non-hormonal contraceptive methods.

**Use in Pregnancy**

**Category B3**

Femoston-Conti is contraindicated during pregnancy. If pregnancy occurs during medication with Femoston-Conti, treatment should be withdrawn immediately.

In animal studies, maternal administration of high doses of estradiol and dydrogesterone (as individual agents) produced urogenital malformations in the offspring. The clinical relevance of these findings is unclear.

The results of most epidemiological studies to date relevant to inadvertent fetal exposure to combinations of estrogens with progestogens indicate no obvious teratogenic or fetotoxic effect. However, there are no adequate data from the use of estradiol / dydrogesterone in pregnant women.

**Use in Lactation**

Estrogen administration to nursing mothers has been shown to decrease the quantity and quality of milk. Detectable amounts of estrogens and progestogens have been found in the milk of lactating mothers receiving these compounds, but the effects on the breastfed infant have not been determined. Hormones, such as estrogens and progestogens should not be taken by nursing mothers.

**Use in Children**

Femoston-Conti 1/5 is not recommended for use in children below age 18 due to insufficient data on safety and efficacy.

**Use in the Elderly**

Of the total number of subjects in the estrogen plus progestogen sub-study of the Women's Health Initiative study, 44% (n = 7320) were 65 years and over, while 6.6% (n = 1,095) were 75 years and over (see ‘CLINICAL TRIALS’). There was a higher incidence of stroke and invasive breast cancer in women 75 and over compared to women less than 75 years of age. In the Women's Health Initiative Memory Study (WHIMS), an ancillary study of WHI, a population of 4,532 women aged 65 to 79 years was randomised to a continuous combined regimen of conjugated estrogens 0.625 mg/day plus medroxyprogesterone acetate 2.5 mg/day or placebo. A population of 2,947 hysterectomised women, aged 65 to 79 years, was randomised to conjugated estrogens (CE 0.625 mg) alone or placebo. In the planned analysis, pooling the events in women receiving CE or CE plus MPA in comparison to those in women on placebo, the overall relative risk (RR) for probable dementia was 1.76 (95% CI 1.19-2.60). In the estrogen- alone group, after an average follow-up of 5.2 years a RR of 1.49 (95% CI 0.83-2.66) for probable dementia was observed compared to placebo. In the estrogen-plus- progestogen group, after an average follow-up of 4 years, a RR of 2.05 (95% CI 1.21-3.48) for probable dementia was observed compared to placebo. Since this study was conducted in women aged 65 to 79 years, it is unknown whether these findings apply to younger postmenopausal women (see ‘PRECAUTIONS - Dementia’).

With respect to efficacy in the approved indications, there have not been sufficient numbers of geriatric patients involved in studies utilising estrogens and progestogens to
determine whether those over 65 years of age differ from younger subjects in their response to estrogens and progestogens.

**Carcinogenicity**

Supra-physiological doses of estradiol have been associated with the induction of tumours in estrogen-dependent target organs in all rodent species tested. The relevance of these findings with respect to humans has not been established. Unopposed estrogen therapy is associated with an increased incidence of endometrial carcinoma, particularly with prolonged use. Concurrent progestogen therapy for a minimum of 12 to 14 days reduces the risk of endometrial hyperplasia.

**Genotoxicity**

Genotoxicity assays with estradiol have shown no changes in the incidence of sister chromatid exchanges, but have shown increased frequency of gene mutation in transformed mouse cells *in vitro*, chromosomal aberrations in Chinese Hamster Ovary cells *in vitro*, and increased aneuploidy in Syrian Hamster Embryo cells and cultured human fibroblasts *in vitro*.

Dydrogesterone did not exhibit any evidence of genotoxicity in gene mutation studies in bacteria or in tests for clastogenic effects in mammalian cells *in vitro* or *in vivo*.

**Interactions with other Medicines**

No interaction studies have been performed.

The efficacy of estrogen and progestogens may be impaired:

The concomitant use of drugs known to induce drug metabolising enzymes, specifically P450 enzymes 2B6, 3A4, 3A5, 3A7, such as anticonvulsants (e.g. Phenobarbital, carbamazepine, phenytoin) and anti-infectives (e.g., rifampicin, rifabutin, nevirapine, efavirenz), may increase the metabolism of estrogen resulting in decreased estrogenic activity.

Ritonavir and nelfinavir, although known as strong inhibitors of CYP450 3A4, A5, A7, by contrast, exhibit inducing properties when used concomitantly with steroid hormones. Clinically, an increased metabolism of estrogens and progestogens may lead to decreased effect and changes in the uterine bleeding profile.

Herbal preparations containing St John's Wort (*Hypericum perforatum*) may induce the metabolism of estrogens and progestogens via the CYP450 3A4 pathway.

Estrogens might interfere with the metabolism of other drugs:

Estrogens may inhibit CYP450 drug metabolising enzymes via competitive inhibition. This is in particular to be considered for substances with a narrow therapeutic index, such as:

- Tacrolimus and ciclosporinA (CYP450 3A4, 3A3)
- Fentanyl (CYP450 3A4)
- Theophylline (CYP450 1A2)

Clinically this may lead to a plasma increase of the affected substance up to toxic levels. Thus, careful drug monitoring for an extended period of time might be necessary and a dosage decrease of tacrolimus, fentanyl, ciclosporin A and theophylline may be necessary.

**Effects on the Ability to Drive and Use Machines**

Femoston-Conti 1/5 has no or negligible influence on the ability to drive and use machines. Note: Femoston-Conti does not cause drowsiness.
ADVERSE EFFECTS

The most commonly reported adverse drug reactions of patients treated with estradiol/dydrogesterone in clinical trials are headache, abdominal pain, breast pain/tenderness and back pain.

Side effects data available from the premarketing clinical trial program are tabulated at a frequency of 1% or more, according to each body system and in descending order of frequency.

As expected, side effects, if they occur, are more common in the first months of treatment. Treatment emergent adverse reactions with Femoston-Conti

Very common (> 10%)
- **Gastrointestinal:** abdominal pain, nausea
- **Reproductive, female:** breast pain, dysmenorrhoea
- **Body as a whole, general:** headache

Common (1-10%)
- **Body as a whole, general:** oedema, weight change
- **Reproductive, female:** intermittent bleeding/spotting

Uncommon (0.1-1%)
- **Reproductive, female:** ovarian cyst

Breast Cancer

For estrogen-only HRT, estimates of relative risk (RR) from a reanalysis of original data from 51 epidemiological studies (in which >80% of HRT use was estrogen-only HRT) and from the epidemiological Million Women Study (MWS) are similar at 1.35 (95% CI 1.21-1.49) and 1.30 (95% CI 1.21-1.40), respectively. The MWS reported that, compared to never users, the use of various types of estrogen-progestogen combined HRT was associated with a higher risk of breast cancer (RR=2.00, 95% CI 1.88-2.12) than use of estrogens alone (RR=1.30, 95% CI 1.21-1.40) or use of tibolone (RR=1.45, 95% CI 1.25-1.68). The absolute risks calculated from the MWS and the WHI trial are presented below:

The MWS has estimated, from the known average incidence of breast cancer in developed countries, that:

For women not using HRT, about 32 in every 1,000 are expected to have breast cancer diagnosed between the ages of 50 and 64 years.

For 1,000 current or recent users of HRT, the number of additional cases during the corresponding period will be:

- For users of estrogen-only replacement therapy
  Between 0 and 3 (best estimate = 1.5) for 5 years’ use
  Between 3 and 7 (best estimate = 5) for 10 years’ use

- For users of estrogen plus progestogen combined HRT
  Between 5 and 7 (best estimate = 6) for 5 years’ use
  Between 18 and 20 (best estimate = 19) for 10 years’ use
The WHI trial estimated that after 5.6 years of follow-up of women between the ages of 50 and 79 years, an additional 8 cases of invasive breast cancer would be due to estrogen-progestogen combined HRT (CE plus MPA) per 10,000 women years. According to calculations from the trial data, it is estimated that:

- For 1,000 women in the placebo group about 16 cases of invasive breast cancer would be diagnosed in 5 years.
- For 1,000 women who used estrogen + progestogen combined HRT (CE plus MPA), the number of additional cases would be between 0 and 9 (best estimate = 4) for 5 years’ use.

The number of additional cases of breast cancer in women who use HRT is broadly similar for women who start HRT irrespective of age at start of use (between the ages of 45-65).

**Endometrial Cancer**

In Women with an intact uterus, the risk of endometrial hyperplasia and endometrial cancer increases with increasing duration of use of unopposed estrogens (see ‘PRECAUTIONS’).

**Ovarian Cancer**

Use of estrogen-only or combined estrogen-progestogen HRT has been associated with a slightly increased risk of having ovarian cancer diagnosed (see ‘PRECAUTIONS’). A meta-analysis from 52 epidemiological studies reported an increased risk of ovarian cancer in women currently using HRT compared to women who have never used HRT (1.43, 95% CI 1.31-1.56). For women aged 50 to 54 years taking 5 years of HRT, this results in about 1 extra case per 2000 users. In women aged 50-54 who are not taking HRT, about 2 women in 2000 will be diagnosed with ovarian cancer over a 5-year period.

**Risk of Venous Thromboembolism**

HRT is associated with an increased risk of developing venous thromboembolism (VTE), i.e. deep vein thrombosis or pulmonary embolism. The occurrence of such an event is more likely in the first year of using HRT (see ‘PRECAUTIONS’).

**Risk of Coronary Artery Disease**

The risk of coronary artery disease is slightly increased in users of combined estrogen-progestogen HRT over the age of 60 (see ‘PRECAUTIONS’).

**Risk of Ischaemic Stroke**

The use of estrogen-progestogen therapy is associated with an increased risk of ischaemic stroke. This relative risk is not dependent on age or on duration of use, but as the baseline risk is strongly age-dependent, the overall risk of stroke in women who use HRT will increase with age (see ‘PRECAUTIONS’).

**Other Adverse Effects**

Other adverse reactions have been reported in association with estrogen/progestogen treatment (including estradiol/dydrogesterone):

- **Neoplasms benign, malignant and unspecified**: Estrogen-dependent neoplasms both benign and malignant, e.g. endometrial cancer, ovarian cancer. Increase in size of progestogen dependent neoplasms, e.g. meningioma.
- **Blood and lymphatic system disorders**: Haemolytic anaemia (very rare)
- **Immune system disorders**: Systemic lupus erythematosus
- **Metabolism and nutrition disorders**: Hypertriglyceridaemia
- **Nervous system disorders**: Probable dementia, chorea (very rare), exacerbation of epilepsy
- **Eye disorders**: Intolerance to contact lenses, steepening of corneal curvature (rare)
Reproductive system and breast disorders: Fibrocystic breast changes, change in cervical erosion (uncommon)
Vascular disorders: Arterial thromboembolism, stroke (very rare)
Gastrointestinal disorders: Pancreatitis (in women with pre-existing hypertriglyceridemia)
Skin and subcutaneous tissue disorders: Chloasma or melasma, which may persist when drug is discontinued (very rare), erythema multiforme (very rare), erythema nodosum (very rare)
Musculoskeletal and connective tissue disorders: Leg cramps (common)
Congenital and familial/genetic disorders: Aggravation of porphyria (very rare)
Investigations: Total thyroid hormones increased
Renal and urinary disorders: Urinary incontinence

DOSAGE AND ADMINISTRATION

One tablet administered orally daily without interruption. When all the tablets in the pack have been taken, another pack is started without interruption (see ‘INDICATIONS’ and ‘PRECAUTIONS’ for treatment duration advice).

If a dose has been forgotten, it should be taken as soon as possible. If more than 12 hours have elapsed, treatment should be continued with the next tablet without taking the forgotten tablet. The likelihood of breakthrough bleeding or spotting may be increased.

Women experiencing a natural menopause should commence treatment with Femoston-Conti 12 months after their last natural menstrual bleed. For surgically induced menopause, treatment may start immediately. Femoston-Conti is intended to prevent stimulation of the endometrium in postmenopausal women, usually resulting in amenorrhoea.

Changing from Sequential HRT

Patients changing from sequential HRT preparations, such as Femoston 1/10 mg or 2/10 mg, to Femoston-Conti should do so at the end of the estrogen plus progestogen phase of the sequential therapy, without a tablet-free interval.

Femoston-Conti should normally be used only in women more than 12-month post-menopause. If the menopausal status is not known (e.g. because of previous use of sequential HRT or oral combination contraceptives) the endogenous estrogen may still be high. This could result in unpredictable bleeding patterns, especially in the first few cycles.

Prevention of bone mineral density loss

Protection appears to be effective for as long as treatment continues, however data on estrogen therapy beyond 10 years are limited. A careful reappraisal of the risk benefit ratio should be undertaken before treatment for longer than 5 – 10 years. For long term use, see ‘PRECAUTIONS’.

The mainstays for decreasing the risk of postmenopausal osteoporosis are weight bearing exercise, adequate calcium and vitamin D intake, and when indicated, pharmacological therapy. Postmenopausal women require an adequate daily intake of elemental calcium. Therefore, when not contraindicated, calcium supplementation may be helpful for women with sub-optimal dietary intake. Vitamin D supplementation may also be required to ensure adequate daily intake in postmenopausal women.

OVERDOSAGE

No acute serious medical effects have been reported in association with an overdosage of either estradiol or dydrogesterone. Possible symptoms following overdosage are similar to the adverse reactions. There are no specific therapeutic recommendations for the management of overdosage. In the event of a large overdose treatment should be
symptomatic. Contact the Poisons Information Centre on 13 11 26 for management of overdose.

PRESENTATION AND STORAGE CONDITIONS
Each pack contains one, two or three, PVC/Al blister strips of:
28 round, biconvex, salmon-coloured, film-coated tablets each containing 1 mg estradiol and 5 mg dydrogesterone bearing the inscriptions "379" on one side.
Store below 30°C.
