AUSTRALIAN PRODUCT INFORMATION – LEFLUNOMIDE APOTEX (LEFLUNOMIDE)

1 NAME OF THE MEDICINE
Leflunomide.

2 AND 3 QUALITATIVE AND QUANTITATIVE COMPOSITION AND PHARMACEUTICAL FORM
Each tablet contains 10 mg or 20 mg of Leflunomide, as the active ingredient.

In addition, each tablet contains the following inactive ingredients: microcrystalline cellulose, lactose monohydrate, maize starch, povidone, crospovidone, colloidal anhydrous silica, magnesium stearate, Opadry II complete film coating system OY-LS-28908 White (PI 4527) (10 mg only), and Opadry Aqueous Film Coating OY-SR-6497 Yellow (PI 3965) (20 mg only).

10 mg tablets
White, round biconvex tablet.

20 mg tablets
Yellow, round biconvex tablets with a scoreline on one side.

4 CLINICAL PARTICULARS

4.1 THERAPEUTIC INDICATIONS
The treatment of:

- Active Rheumatoid Arthritis.
- Active Psoriatic Arthritis. This medicine is not indicated for the treatment of psoriasis that is not associated with manifestations of arthritic disease.

The combined use of leflunomide with other Disease Modifying Anti-Rheumatic Drugs (DMARDs) has not been adequately studied (see Section 4.4 Special Warnings and Precautions for Use).

4.2 DOSE AND METHOD OF ADMINISTRATION

Rheumatoid Arthritis & Psoriatic Arthritis

Loading Dose
Leflunomide therapy is started with a loading dose of 100 mg (five 20 mg tablets or ten 10 mg tablets) once daily for three days. Avoiding a loading dose may decrease the risk of adverse events if leflunomide is used in combination with methotrexate. This could be especially important for patients at increased risk of haematological or hepatic toxicity, such as those receiving concomitant treatment with methotrexate or other immunosuppressive agents or on such medications in the recent past. (See Section 4.4 Special Warnings and Precautions for Use - Concomitant use with hepatotoxic and haematotoxic agents, and Hepatotoxicity.)
Maintenance Dose

The recommended maintenance dose for rheumatoid arthritis is leflunomide 20 mg once daily. Doses higher than 20 mg/day are not recommended. If dosing at 20 mg/day is not well tolerated, the dose may be decreased to 10 mg daily.

The recommended maintenance dose for psoriatic arthritis is 20 mg once daily.

Liver enzymes and haematological parameters must be monitored and dose adjustments or discontinuation may be necessary (see Section 4.4 Special Warnings and Precautions for Use).

Due to the prolonged half-life of the active metabolite of leflunomide, patients should be carefully observed after dose reduction since it may take several weeks for metabolite levels to decline.

Leflunomide tablets should be swallowed whole with sufficient liquid. Absorption of leflunomide is not affected if it is taken with food. An improvement in the patient's rheumatoid condition may begin as early as four weeks after starting therapy with leflunomide, however, there may be further improvement in the condition after four to six months of treatment.

At present there is not enough experience available to make dosage recommendations for patients with a serum creatinine concentration of > 133 micromol/L (1.5 mg/dL).

No dosage adjustment is required in the elderly.

Compatibility with Other Anti-rheumatic Drugs

If the patient is already receiving NSAIDs and/or low dose corticosteroids, these may be continued after starting leflunomide.

See Section 4.5 Interactions with Other Medicines and Other Forms of Interactions for information about co-administration with methotrexate and other hepatotoxic and haematotoxic drugs.

4.3 CONTRAINDICATIONS

- patients with hypersensitivity to leflunomide or to any of the excipients in the tablets
- patients with severe immunodeficiency states, e.g. AIDS
- patients with significantly impaired bone marrow function or significant anaemia, leukopenia or thrombocytopenia due to causes other than rheumatoid arthritis or psoriatic arthritis
- patients with severe, uncontrolled infections
- patients with impairment of liver function
- pregnant women
- women of childbearing potential who are not using reliable contraception during treatment with leflunomide and for a certain period of time thereafter, as long as the plasma levels of the active metabolite are above 0.02 mg/L, unless undergoing washout treatment (see Section 4.6 Fertility, Pregnancy and Lactation - Use in Pregnancy)
- women who are breast-feeding
patients with severe hypoproteinaemia

patients who have or have had Stevens-Johnson syndrome, toxic epidermal necrolysis or erythema multiforme

4.4 SPECIAL WARNINGS AND PRECAUTIONS FOR USE

Concomitant Use with Hepatotoxic and Haematotoxic Agents

Increased monitoring frequency is advised when leflunomide is used in combination with other hepatotoxic and haematotoxic agents (see Section 4.5 Interactions with Other Medicines and other Forms of Interactions). Pancytopenia is a rare event, which has been reported with leflunomide, with a fatal outcome in isolated cases. These events have been reported most frequently in cases of recent, concomitant or subsequent use of potentially myelotoxic/haematotoxic agents, such as methotrexate. (The incidence of pancytopenia associated with methotrexate alone is reported in published literature to be between 0.6% to 2.1%). If the patient has any evidence of pancytopenia on routine haematological monitoring, stop leflunomide, commence washout procedure and continue close haematological monitoring until confirmed resolution (see section 4.9 Overdose).

Concomitant treatment with methotrexate and/or other hepatotoxic medications is associated with an increased risk of serious hepatic reactions. To minimise the risk of serious adverse reactions, it is essential that all monitoring recommendations are strictly adhered to.

Due to the prolonged half-life of A771726 (usually 1 to 4 weeks), adverse reactions may occur or persist even after leflunomide administration has been discontinued (see Section 4.8 Adverse Effects (Undesirable Effects)). If a severe adverse reaction to leflunomide occurs, or if for any reason A771726 needs to be cleared rapidly from the body, cholestyramine or charcoal has to be initiated as described in the Overdose section 4.9 and continued/repeated as clinically necessary. For suspected severe immunological/allergic reactions, more prolonged cholestyramine or charcoal administration may be necessary to achieve rapid and sufficient clearance. Washout procedures must be performed in circumstances when serious effects occur (e.g. hepatotoxicity, haematotoxicity or allergic reactions), in the case of desired or unintended pregnancy and if for any other reason A771726 needs to be cleared rapidly from the body.

Haematological Monitoring

A complete blood cell count (including differential white blood cell count and platelets) should be performed in all patients before the start of leflunomide treatment and monthly for the first 6 months, followed by 6–8 weeks thereafter. If used with concomitant methotrexate and/or other potential immunosuppressives, chronic monitoring should be monthly.

In patients with pre-existing anaemia, leukopenia and/or thrombocytopenia, as well as in patients with impaired bone marrow function or those at risk of bone marrow suppression, the risk for occurrence of haematological reactions is increased.

Hepatotoxicity

In clinical trials, leflunomide treatment was associated with elevations of liver function tests, primarily ALT (SGPT) and AST (SGOT). These effects were generally reversible. Most transaminase elevations were mild (≤ 2 x ULN) and usually resolved while continuing treatment. Clinically significant elevations (> 2 and ≤ 3 x ULN) were less common and were generally asymptomatic and reversible with dose reduction or, if persistent, discontinuation of leflunomide. More marked elevations (> 3 x ULN) occurred rarely and usually reversed with dose reduction; persistent elevations resolved after discontinuation of leflunomide.
Overall, persistent elevations after dose reduction were uncommon and were usually associated with concomitant NSAID use. Biopsy data did not suggest that leflunomide was associated with the development of cirrhosis or hepatic fibrosis.

Very rare cases of severe liver injury, with fatal outcome in isolated cases, have been reported during treatment with leflunomide. Most of the cases occurred within the first 6 months of treatment. Although confounding factors were present in many cases, a causal relationship to leflunomide cannot be excluded. It is considered essential that monitoring recommendations are strictly adhered to (see Section 4.4 Special Warnings and Precautions for Use - Liver Function Monitoring).

In the US4001 combination study of leflunomide in patients with persistent active rheumatoid arthritis receiving stable background methotrexate for at least 6 months without liver enzyme elevation (n = 263), 226 patients received up to 48 weeks the addition of leflunomide to methotrexate therapy. In this study, patients with inadequate response to a stable dose of methotrexate for 6 months, were administered leflunomide with a loading dose of one 100 mg tablet daily for 2 days and thereafter, patients received a maintenance dose of 10 mg daily. These doses are both lower than the recommended initial dose of monotherapy with leflunomide. If dosing at 10 mg/day was not well tolerated clinically, the dose was decreased to 10 mg of leflunomide every other day. If the 10 mg daily dose was tolerated, but disease activity persisted at 8 weeks or thereafter, the dose of leflunomide was increased to a maximum of 20 mg daily. In the 6-month placebo-controlled study phase the incidence of ALT elevations > 3-fold ULN on leflunomide added to methotrexate therapy was 3.8% versus 0.8% when placebo was added to methotrexate. (The incidence of > 3-fold ULN ALT elevations for leflunomide monotherapy in study US301, MN301 and MN302 was 1.5% to 4.4%). ALT elevations > 2-fold ULN reversed to ≤ 2-fold ULN and normalized to < 1.2-fold ULN with leflunomide dose reduction or discontinuation. Milder elevations of > 1.2 to < 2-fold ULN normalized without change in leflunomide dose in most cases, although a minority normalized after dose reduction or discontinuation.

Liver Function Monitoring

ALT and AST must be checked before the start of leflunomide treatment and monitored at monthly or more frequent intervals for at least the first 6 months and then, if stable, every 6 - 8 weeks thereafter. In addition, if leflunomide and methotrexate are given concomitantly, ALT, AST and serum albumin testing must be performed monthly. For confirmed ALT or AST elevations between 2 and 3-fold the ULN, dose reduction may allow continued administration of leflunomide under close monitoring. For minor elevations in ALT or AST (< 2-fold ULN), repeat testing in 2 - 4 weeks. For moderate elevations in ALT or AST (> 2-fold but < 3-fold ULN), closely monitor, with LFTs every 2 - 4 weeks and dosage reduction. If ALT or AST elevations between 2 and 3-fold ULN persist or if ALT or AST elevations of more than 3-fold ULN are present, leflunomide should be discontinued. Cholestyramine or activated charcoal should be administered to more rapidly lower A771726 levels, with close monitoring including retreatment with cholestyramine or activated charcoal as indicated.

Use in hepatic impairment

See Section 5.2 Pharmacokinetic Properties - Hepatic Impairment

Use in renal impairment

Leflunomide was administered as a single oral 100 mg dose to 3 haemodialysis patients and 3 patients on continuous peritoneal dialysis (CAPD). The pharmacokinetics of A771726 in CAPD subjects appeared to be similar to healthy volunteers. A more rapid elimination of A771726 was observed in haemodialysis subjects which was not due to extraction of drug in the dialysate but instead to displacement of protein binding. Caution should be used when
leflunomide is administered to patients with renal impairment (see Section 5.2 Pharmacokinetic Properties - Special Populations).

Infections

It is known that medications with immunosuppressive properties may cause patients to be more susceptible to infections, including opportunistic infections, and these may be more severe in nature. Infections may, therefore, require early and vigorous treatment. In the event that severe, uncontrolled infections occur, it may be necessary to stop leflunomide and administer a washout with cholestyramine (see Section 4.9 Overdose).

Rare cases of Progressive Multifocal Leukoencephalopathy (PML) have been reported in patients receiving leflunomide among other suppressants.

Respiratory

Interstitial lung disease has been reported rarely during treatment with leflunomide (see Section 4.8 Adverse Effects (Undesirable Effects)). The risk of its occurrence is increased in patients with a history of interstitial lung disease. Interstitial lung disease is a potentially fatal disorder, which may occur acutely during therapy. New onset or worsening pulmonary symptoms, such as cough and dyspnoea, with or without associated fever, may be a reason for further investigation. Discontinuation of the therapy and implementation of a washout with cholestyramine (see Section 4.9 Overdose) may be appropriate.

Patients should be informed about the early warning signs of interstitial lung disease and asked to contact their physician as soon as possible if these symptoms appear or worsen during therapy.

Peripheral Neuropathy

Rare reports of peripheral neuropathy occurring during leflunomide treatment have been received. Upon discontinuation of leflunomide, most patients recovered; however, for some patients, symptoms persisted.

The risk of peripheral neuropathy may be increased in older patients (>60 years of age) who are diabetic and/or taking concomitant neurotoxic agents.

Discontinuation of leflunomide should be considered if a patient develops peripheral neuropathy; and the washout procedure initiated (see Section 4.9 Overdose).

Immunosuppression

Although there is no clinical experience in the following patient populations, leflunomide is not recommended for patients with severe immunodeficiency, bone marrow dysplasia or severe uncontrolled infections because of the theoretical potential for immunosuppression. In the event that a serious infection occurs, it may be necessary to interrupt therapy with leflunomide and administer cholestyramine or charcoal (see section 4.9 Overdose). Rarely, severe infections including sepsis, which may be fatal, have been reported in patients receiving leflunomide. Most of the reports were confounded by concomitant immunosuppressant therapy and/or co-morbid illness which, in addition to rheumatoid disease, may predispose patients to infection.

In post-marketing experience, there have been reports of pancytopenia (rare), agranulocytosis (very rare) and thrombocytopenia (rare) in patients receiving leflunomide. (see Section 4.4 Special Warnings and Precautions for Use - Concomitant use with
hepatotoxic and haematotoxic agents, including methotrexate section). In most of these cases, patients received concomitant treatment with methotrexate or other immunosuppressive agents or they had recently discontinued these therapies. Some cases had a prior history of significant haematologic abnormality. If leflunomide is used in such patients, it should be done with caution and with frequent haematologic monitoring (see Section 4.4 Special Warnings and Precautions for Use - Haematological Monitoring). The use of leflunomide in combination therapy with methotrexate has not been adequately studied in a controlled setting.

If evidence of bone marrow suppression occurs in a patient taking leflunomide, treatment with leflunomide should be stopped and cholestyramine or charcoal should be used to reduce the plasma concentration of leflunomide (see Section 4.9 Overdose).

In any situation in which the decision is made to switch from leflunomide to another anti-rheumatic agent with a known potential for haematologic suppression, it would be prudent to monitor for haematologic toxicity, because there will be overlap of systemic exposure to both compounds. Leflunomide washout with cholestyramine or charcoal may decrease this risk, but also may induce disease worsening if the patient had been responding to leflunomide treatment.

In dogs treated with leflunomide, a delayed healing of accidental cornea lesions was observed. This effect may be attributed to the immunosuppressive effect of leflunomide. Its clinical relevance is, however, unclear.

Patients with tuberculin reactivity must be carefully monitored because of the risk of tuberculosis reactivation.

Antigenicity

Leflunomide was not antigenic in the active systemic and passive cutaneous anaphylaxis test in guinea pigs and was devoid of sensitising properties.

Blood Pressure Monitoring

Blood pressure should be checked before the start of leflunomide treatment and periodically thereafter.

Use in Males

Available information does not suggest that leflunomide would be associated with an increased risk of male-mediated foetal toxicity. However, animal studies to evaluate this specific risk have not been conducted. To minimize any possible risk, men wishing to father a child should consider discontinuing use of leflunomide and taking cholestyramine 8 g 3 times daily for 11 days or 50 g activated charcoal 4 times daily for 11 days.

In either case the A771726 plasma concentration is then measured for the first time. Thereafter, the A771726 plasma concentration must be determined again after an interval of at least 14 days. If both plasma concentrations are below 0.2 mg/L, and after a waiting period of at least 3 months, the risk of foetal toxicity is very low.

Use in the elderly

Leflunomide should be used with caution in patients over 75 years as its safety and efficacy have not been studied in this age group.
Paediatric use
The safety and effectiveness of leflunomide in paediatric patients have not been fully evaluated. Leflunomide is not recommended for use in patients under 18 years (see Section 5.1 Pharmacodynamic Properties - Clinical Trials and Section 4.8 Adverse Effects (Undesirable Effects)).

Effects on laboratory tests
No data available.

Skin Reactions
In case of ulcerative stomatitis, leflunomide administration should be discontinued. Very rare cases of Stevens-Johnson syndrome or toxic epidermal necrolysis have been reported in patients treated with leflunomide. As soon as skin and/or mucosal reactions are observed which raise the suspicion of such severe reactions, leflunomide and any other possible associated medication must be discontinued and cholestyramine or charcoal should be used immediately to reduce the plasma concentration of leflunomide (see Section 4.9 Overdose). A complete washout is essential in such cases. In such cases re-exposure to leflunomide is contraindicated.

Mutagenicity
Leflunomide (A771726) was not mutagenic in bacteria (Salmonella typhimurium and Escherichia coli) or Chinese hamster ovary cells, did not cause chromosomal damage in vivo (mouse and Chinese hamster bone marrow cells) and did not induce unscheduled synthesis of DNA in vitro in mammalian cells. A minor metabolite of leflunomide, trifluoromethylaniline, was mutagenic and caused chromosomal damage in in vitro assays, but it did not cause chromosomal damage in vivo (Chinese hamster bone marrow cells) at concentrations higher than those expected in humans.

4.5 INTERACTIONS WITH OTHER MEDICINES AND OTHER FORMS OF INTERACTIONS
The enzymes involved in the metabolism of leflunomide and its metabolites are not precisely known. In vitro studies indicate that A771726 inhibits cytochrome P450 2C9 (CYP2C9) activity. Caution is advised when leflunomide is given together with drugs, other than NSAIDs, metabolised by CYP2C9 such as phenytoin, warfarin and tolbutamide (see below). The extensive protein binding of A771726 could lead to displacement of other highly-bound drugs.

Cimetidine
An in vivo interaction study with cimetidine (non-specific cytochrome P450 inhibitor) has demonstrated a lack of a significant interaction.

Rifampicin
Following concomitant administration of a single dose of leflunomide to subjects receiving multiple doses of rifampicin (non-specific cytochrome P450 inducer) A771726 peak levels were increased by approximately 40%, whereas the AUC was not significantly changed. The mechanism of this effect is unclear. Because of the potential for A771726 levels to continue to increase with multiple dosing, caution should be exercised if patients are to be receiving both leflunomide and rifampicin.
Warfarin

Increased prothrombin time when leflunomide and warfarin were co-administered has been rarely reported.

*In vitro* plasma protein binding interaction studies with warfarin at clinically relevant concentrations showed no interaction. This does not exclude the possibility of an interaction by other means, such as inhibition of drug metabolism. This has not been studied.

NSAIDs

NSAIDS (including COX-2 inhibitors) are known to cause hepatotoxicity, therefore caution is advised when leflunomide is used concomitantly (see **Section 4.4 Special Warnings and Precautions for Use**). Studies showed that ibuprofen and diclofenac did not displace A771726. A771726 displaced ibuprofen and diclofenac and the unbound fraction of these drugs was increased by 10 - 50%. In clinical trials, no safety problems were observed when leflunomide and NSAIDs metabolised by CYP2C9 were co-administered.

Tolbutamide

In *in vitro* studies, A771726 was shown to cause increases ranging from 13% to 50% in the free fraction of tolbutamide at concentrations in the clinical range. The clinical significance of this finding is unknown. The unbound fraction of A771726 was increased 2 - 3 fold in the presence of tolbutamide.

Methotrexate

In a small (n = 30) combination study of leflunomide (10 - 20 mg/day) with methotrexate (10 - 25 mg/week) co-administration increased the risk of hepatotoxicity. Baseline disease characteristics reflect a patient population with active RA (average tender and swollen joint count of 16) and longstanding disease (mean duration 13.6 years). No pharmacokinetic interaction was identified. A greater than 3-fold increase in liver enzymes was seen in five patients. All of these increases resolved, two with continuation of both drugs and three after discontinuation of leflunomide. A 2 to 3-fold increase was seen in an additional 5 patients. All elevations resolved, two with continuation of both drugs and three after discontinuation of leflunomide. Three patients met ACR criteria for liver biopsy (1: Roegnik Grade I, 2: Roegnik Grade IIIa). (see **Section 4.4 Special Warnings and Precautions for Use - Concomitant Use with Hepatotoxic and Haematotoxic Agents** and **Hepatotoxicity** sections).

Hepatotoxic and Haematotoxic Drugs

Increased side effects may occur when leflunomide is given concomitantly with hepatotoxic or haematotoxic drugs or when leflunomide treatment is followed by such drugs without a washout period. The possibility of additive risks of side effects may persist for a long time after switching treatments. Therefore, the initiation of leflunomide treatment has to be carefully considered given these benefit/risk aspects.

Due to a potential for additive hepatotoxic effects, it is recommended that excessive alcohol consumption is avoided during treatment with leflunomide.

Oral contraceptives

When leflunomide was administered concomitantly with a low-dose oral contraceptive to healthy female volunteers, there was no effect on either the anti-ovulatory activity of the contraceptive or the pharmacokinetics of A771726.
Vaccinations

No clinical data are available on the efficacy and safety of vaccinations under leflunomide treatment. Vaccination with live vaccines is, however, not recommended. A live vaccine should only be given after a period of at least 6 months has elapsed after stopping leflunomide.

Cholestyramine and Activated Charcoal

It is recommended that patients receiving leflunomide are not treated with cholestyramine or activated charcoal because this leads to a rapid and significant decrease in plasma A771726 (the active metabolite of leflunomide) concentration. The mechanism is thought to be by interruption of enterohepatic recycling and/or gastrointestinal dialysis of A771726.

4.6 FERTILITY, PREGNANCY AND LACTATION

Effects on fertility

Oral administration of leflunomide at doses up to 4 mg/kg/day [plasma A771726 concentrations (AUC) about 10–25 times lower than that expected in humans] in rats had no effect on fertility, however, impairment of spermatogenesis has been observed in rats, dogs and mice treated with oral leflunomide at higher doses or for longer periods (plasma A771726 AUC similar to or much lower than that expected in humans).

Use in pregnancy (Category X)

Category X: Drugs which have such a high risk of causing permanent damage to the foetus that they should not be used in pregnancy or when there is a possibility of pregnancy.

As A771726 is teratogenic in rats and rabbits, it may cause foetal harm in humans. Leflunomide must not be given to pregnant women, or women of childbearing potential who are not using reliable contraception during treatment with leflunomide and for a certain period of time thereafter as long as the plasma levels of the active metabolite are above 0.02 mg/L (Waiting Period; see below), unless undergoing washout treatment (Washout Procedure; see below). Pregnancy must be excluded before the start of treatment with leflunomide.

It is recommended that women of childbearing potential only receive leflunomide after it has been confirmed that they are using a reliable form of contraception. In a study in which leflunomide was given to healthy female volunteers concomitantly with a triphasic oral contraceptive pill containing 30 μg ethinyloestradiol, there was no reduction in contraceptive activity of the pill and A771726 pharmacokinetics were within predicted ranges.

Patients must be advised that if there is any delay in the onset of menses or any other reason to suspect pregnancy, they must notify their physician immediately to test for pregnancy. If the test is positive, the physician and patient must discuss the risk to the foetus. It is possible that by rapidly lowering the blood level of the active metabolite at the first delay of menses, using the drug elimination procedure described below, the risk to the foetus may be decreased.

In a small prospective study in women (n = 64) who became inadvertently pregnant while taking leflunomide for no more than three weeks after conception and followed by a drug elimination procedure, no significant differences (p = 0.03) were observed in the overall rate of major structural defects (5.4%) compared to either of the comparison groups (4.2% in the diseased matched group [n = 108] and 4.2% in healthy pregnant women [n = 78]).
Waiting Period

A771726 plasma levels can be expected to be above 0.02 mg/L for a prolonged period. The concentration may be expected to decrease below 0.02 mg/L about 2 years after stopping the treatment with leflunomide.

After a 2 year waiting period, the A771726 plasma concentration is measured for the first time.

Thereafter, the A771726 plasma concentration must be determined again after an interval of at least 14 days. If both plasma concentrations are below 0.02 mg/L no teratogenic risk is to be expected.

Washout Procedure

For women who have been treated with leflunomide and who wish to become pregnant, one of the following washout procedures is recommended prior to conception after stopping treatment with leflunomide:

- cholestyramine 8 g is administered 3 times daily for a cumulative period of 11 days;
- alternatively, 50 g of activated charcoal is administered 4 times daily for a total period of 11 days.

The 11 days do not need to be consecutive unless there is a need to lower the A771726 plasma level rapidly. Both cholestyramine and activated charcoal may influence the absorption of estrogens and progestogens such that reliable contraception with oral contraceptives may not be guaranteed during the washout procedure with cholestyramine and activated charcoal. Use of alternative contraceptive methods is recommended.

Plasma Monitoring

After the washout procedure has been performed, A771726 plasma levels of < 0.02 mg/L must be verified by 2 separate tests at least 14 days apart and a waiting period of one-and-a-half months between the first occurrence of a plasma concentration below 0.2 mg/L and fertilisation is required. Human plasma levels of the active metabolite less than 0.02 mg/L are expected to have minimal risk based on available data. Without the drug elimination procedure, it may take up to 2 years to reach A771726 levels < 0.02 mg/L (after stopping treatment with leflunomide due to individual variation in drug clearance. However, verification of A771726 levels < 0.02 mg/L by 2 separate tests at an interval of at least 14 days is required.

Use in lactation

Animal studies indicate that leflunomide or its metabolites pass into breast milk. Therefore women must not breast feed while they are receiving leflunomide.

4.7 EFFECTS ON ABILITY TO DRIVE AND USE MACHINES

The effects of this medicine on a person's ability to drive and use machines were not assessed as part of its registration.
4.8 ADVERSE EFFECTS (UNDISIRABLE EFFECTS)

In controlled studies, the following adverse events were reported, regardless of causality. Differences between leflunomide and placebo were observed for diarrhoea, elevated liver enzymes (ALT and AST), hair loss and rash.

Table 1: Percentage of patients with adverse events ≥ 3% in any leflunomide treated group

* Only 10% of patients in MN302 received folate. All patients in US301 received folate.
1 Includes all controlled and uncontrolled trials with leflunomide.
2 Hypertension as a pre-existing condition was over-represented in all leflunomide treatment groups in Phase III trials. Analysis of new onset hypertension revealed no difference among the treatment groups.

In addition, the following adverse events have been reported in 1% to 3% of the RA patients in the leflunomide treatment group in controlled clinical trials.

Urogenital System: albuminuria, cystitis, dysuria, hematuria, menstrual disorder, vaginal moniliasis, prostate disorder, urinary frequency.

Other less common adverse events seen in clinical trials include: 1 case of anaphylactic reaction occurred in Phase II following rechallenge of drug after withdrawal due to rash (rare); urticaria, transient thrombocytopenia (uncommon), eosinophilia (rare); and leukopenia $< 2 \times 10^9/L$ (rare). A causal relationship of these events to leflunomide has not been established.

Mild hyperlipidaemia may occur. Uric acid levels usually decrease due to a uricosuric effect. Laboratory findings for which a clinical relevance could not be established include small increases in LDH and CK, and a small decrease in phosphate.

The overall incidence of infections in clinical studies was comparable between patients taking leflunomide and those taking placebo. Immunosuppressive medications are, however, known to increase susceptibility to infections (see Section 4.4 Special Warnings and Precautions for Use). In clinical studies, the incidence of rhinitis and bronchitis (5% vs 2%) and pneumonia (3% vs 0%) was slightly increased in patients treated with leflunomide compared to placebo. The overall incidence of infections was comparable between leflunomide and placebo. The risk of malignancy, particularly lymphoproliferative disorders, is also known to be increased with use of some immunosuppressive drugs.

When significant side effects occur, the dosage of leflunomide may be reduced or treatment with the drug stopped.

Adverse events in paediatric patients with polyarticular course JRA

The safety of leflunomide was studied in 74 patients with polyarticular course JRA, ranging in age from 3 to 17 years (47 patients from the active-controlled study and 27 from the open-label safety and pharmacokinetic study). The most common adverse events included abdominal pain, diarrhoea, nausea, vomiting, oral ulcers, upper respiratory tract infections, alopecia, rash, headache and dizziness. Less common adverse events included anaemia, hypertension and weight loss. Fourteen paediatric patients experience ALT and/or AST elevations, nine between 1.2 and 3-fold the upper limit of normal and five between 3 and 8-fold the upper limit of normal.

Post Marketing Data

Adverse reactions reported during the post-marketing period are detailed below: These reactions are classified within body system categories using the following definitions:

</tbody>
</table>

Allergic reactions, skin and appendages

Common: Mild allergic reactions (including maculopapular and other rashes), pruritus, eczema, dry skin, increased hair loss.

Uncommon: Urticaria.
Very rare: Severe anaphylactoid reactions. Stevens-Johnson syndrome, toxic epidermal necrolysis, erythema multiforme. In case reports received so far, a casual relationship with leflunomide treatment could not be established, but cannot be excluded. Vasculitis, including cutaneous necrotising vasculitis. Due to the underlying disease, a causal relationship could not be established.

**Haemic and lymphatic system**

**Common:** Leukopenia (leukocytes > 2 G/L).

**Uncommon:** Thrombocytopenia with platelet count < 100 x 10^9 /L (< 100G/L).

**Rare:** Eosinophilia, leukopenia (leukocytes < 2 G/L), pancytopenia.

**Very rare:** Agranulocytosis.

**Liver**

**Common:** Elevation of liver parameters (transaminases [especially ALT], less often gamma-GT, alkaline phosphatase, bilirubin).

**Rare:** Hepatitis, jaundice/cholestatis.

**Very rare:** Severe liver injury (such as hepatic failure and acute hepatic necrosis) that may be fatal, pancreatitis.

**Infection**

**Rare:** Severe infections, including opportunistic infections, and sepsis, which may be fatal. (Most of the case reports were confounded by concomitant immunosuppressant therapy and/or comorbid illness, in addition to rheumatoid disease, which may predispose patients to infection).

**Cardiovascular**

**Common:** Increase in blood pressure.

**Rare:** Severe increase in blood pressure.

**Respiratory, thoracic and mediastinal disorders**

**Rare:** Interstitial lung disease (including interstitial pneumonitis), which may be fatal.

**Nervous system**

**Common:** Headache, dizziness, paraesthesia.

**Uncommon:** Taste disturbances, anxiety.

**Very rare:** Peripheral neuropathy.

**Gastrointestinal Disorders**

**Common:** Diarrhoea, nausea, vomiting, oral mucosal disorders (e.g. aphthous stomatitis, mouth ulceration), abdominal pain.
Musculoskeletal

Common: Tenosynovitis.

Uncommon: Tendon rupture.

Reproduction System:

Not known: Marginal (reversible) decreases in sperm concentration, total sperm count, and rapid progressive motility.

Other

Common: Weight loss, asthenia, anorexia.

Uncommon: Hypophosphataemia.

Not known: Hypouricemia.

Not known: Renal failure

Recent, concomitant or consecutive use of potentially myelotoxic agents may be associated with a higher risk of haematological effects.

In most reported cases of pancytopenia, SJS and TEN, co-medication was given which is associated with the risk of pancytopenia or SJS or TEN.

Very rare cases of severe liver injury, with fatal outcome in isolated cases, have been reported during treatment with leflunomide. This risk may be increased when leflunomide is combined with other DMARDs. Most of the cases occurred within the first 6 months of treatment. Although confounding factors were present in many cases, a causal relationship to leflunomide cannot be excluded. It is considered essential that monitoring recommendations are strictly adhered to.

Reporting suspected adverse effects

Reporting suspected adverse reactions after registration of the medicinal product is important. It allows continued monitoring of the benefit-risk balance of the medicinal product. Healthcare professionals are asked to report any suspected adverse reactions at http://www.tga.gov.au/reporting-problems or contact Apotex Medical Information enquiries/Adverse Drug Reaction Reporting on 1800 195 055.

4.9 OVERDOSE

Symptoms

There have been reports of chronic overdose in patients taking leflunomide at daily dose up to five times the recommended daily dose and reports of acute overdose. There were no adverse events reported in the majority of case reports of overdose. Adverse events were consistent with the safety profile for leflunomide. The most frequent adverse events observed were diarrhoea, abdominal pain, leukopenia, anaemia and elevated liver function tests.
Treatment

In the event of a significant overdose or toxicity, cholestyramine or charcoal administration is recommended to accelerate elimination. Cholestyramine given orally at a dose of 8 g three times a day for 24 hours to three healthy volunteers decreased plasma levels of A771726 by approximately 40% in 24 hours and by 49 - 65% in 48 hours.

Administration of activated charcoal (powder made into a suspension) orally or via nasogastric tube (50 g every 6 hours for 24 hours) has been shown to reduce plasma concentrations of the active metabolite A771726 by 37% in 24 hours and by 48% in 48 hours.

These washout procedures may be repeated if clinically necessary.

Studies with both haemodialysis and CAPD (chronic ambulatory peritoneal dialysis) indicated that A771726 the primary metabolite of leflunomide is not dialyzable.

For information on the management of overdose, contact the Poisons Information Centre on 13 11 26 (Australia).

5 PHARMACOLOGICAL PROPERTIES

5.1 PHARMACODYNAMIC PROPERTIES

Mechanism of action

Leflunomide is an isoxazole immunomodulatory agent which is effective in animal models of arthritis and other autoimmune diseases, allergy and transplantation. In vivo, leflunomide is rapidly metabolized to the ring opened form, A771726, which is the active drug. It has immunomodulating/ immunosuppressive characteristics, acts as an anti-proliferative agent and displays weak anti-inflammatory properties. The anti-proliferative activity is reversed by the addition of uridine to the cell culture, indicating that A771726 acts at the level of the pyrimidine biosynthesis pathway. Binding studies using radio-labelled ligand demonstrate that the active metabolite binds to and inhibits the human enzyme dihydroorotate dehydrogenase (DHODH, an enzyme involved in de novo pyrimidine synthesis). Together, these data suggest that, in vivo, at concentrations achievable in patients receiving leflunomide, pyrimidine synthesis in lymphocytes and other rapidly dividing cell populations may be inhibited. Further, the inhibition of tyrosine kinase activity has been reported, for both in vitro and in vivo situations. The in vitro activity does not seem to be mediated directly through enzyme inhibition and takes place only at much higher concentrations of A771726 than is necessary for the inhibition of DHODH. Leflunomide has demonstrated prophylactic and therapeutic effects in animal models of autoimmune disease. In animal models of chronic graft versus host disease and solid organ graft rejection, leflunomide has prolonged rejection time or reversed ongoing rejection reactions. In a model of experimental septicemia, leflunomide did not alter the resistance of mice to bacterial pathogens.

Clinical trials

Adult Rheumatoid Arthritis

The efficacy of leflunomide in the treatment of rheumatoid arthritis has been demonstrated in three large, multi-centre, long-term clinical trials against placebo (PL), sulfasalazine (SSZ) and methotrexate (MTX). Of the patients receiving leflunomide, the majority received it for more than 336 days. The highest doses used for an extended period in the trials were leflunomide 20 mg/day, SSZ 2 g/day and MTX 15 mg/week. Study MN301 (leflunomide vs placebo vs sulfasalazine) was conducted in 2 parts: a 6-month comparison of the safety and
efficacy of leflunomide vs placebo vs sulfasalazine followed by a 6-month extension study (MN303) to evaluate the effect of leflunomide on the progression of rheumatoid arthritis, in comparison to SSZ, by using X-rays of hands and feet to assess joint destruction. Study US301 (leflunomide vs placebo vs methotrexate with concomitant folic acid) was designed to compare the efficacy and safety of leflunomide in patients with active rheumatoid arthritis who had never previously received methotrexate. Study MN302 (leflunomide vs methotrexate without concomitant folic acid) was designed to compare the efficacy and safety of leflunomide vs methotrexate in patients with rheumatoid arthritis.

**ACR Criteria**

The outcome measures in these trials were: the “ACR Responder” rates over time, the “ACR Success” rates per treatment group, X-ray evaluation of disease progression, and health-related quality of life measures. An “ACR 20 Responder”, based upon American College of Rheumatology (ACR) criteria, is a patient with ≥ 20% improvement in both tender and swollen joint count and in 3 of the following 5 criteria: physician global assessment, patient global assessment, function/disability measure, visual analog pain scale and erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP). Similarly, an “ACR 50 Responder” and an “ACR 70 Responder” are respectively patients with ≥ 50% and ≥ 70% improvement in both tender and swollen joint count and in 3 of the following 5 criteria: physician global assessment, patient global assessment, function/disability measure, visual analog pain scale and ESR or CRP. An “ACR Success” is a patient who completes the trial and is an ACR Responder at the trial endpoint.

The clinical trials demonstrated a significant decrease in tender and swollen joint counts and scores, decreased morning stiffness and pain, improvement in patient and physician global assessments, increase in functional ability and improvement in quality of life [as measured by the Health Assessment Questionnaire (HAQ) and Modified Health Assessment Questionnaire (MHAQ)], retardation of joint destruction (as documented by X-ray analysis measuring both erosions and joint space narrowing), and a decrease in erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and rheumatoid factor (RF) levels. Clinical improvement started at approximately 4 weeks, usually stabilised within 4 to 6 months and was maintained for the duration of treatment.

Leflunomide demonstrated a consistent degree of efficacy across the 3 controlled trials. Leflunomide was statistically significantly superior to placebo in reducing the signs and symptoms of RA. ACR 20 successes for leflunomide treatment in US301 and MN301 were approximately twice that seen in placebo patients: 41% and 49% respectively in leflunomide-treated patients compared to 19% and 29% respectively in placebo-treated patients. The figure 1 below displays ACR 20 Responder rates for each treatment group at endpoint.

ACR 20, 50, and 70% response rates in all treatment groups of the US301 trial are shown in the figure below. In US301, the ACR 20% response rate of patients treated with leflunomide was significantly increased from that seen in placebo-treated patients and similar to that seen in patients treated with methotrexate. Similarly, ACR 50% and 70% responses were approximately two times higher in patients treated with leflunomide or methotrexate than in patients who received placebo.

**Figure 2: ACR response rates in US301**

![ACR Response Rates in US301](image)

** p < 0.01 vs Placebo, † p < 0.05 vs MTX
ACR Response Over Time

ACR 20 Responder rate (%) vs Time in US 301 is shown in the figure 3 below. This figure shows that:

- Leflunomide treatment effect was evident by 1 month, stabilized by 3 - 6 months and continued throughout the course of treatment.
- Area Under Curve (AUC) analysis of ACR Responders vs Time demonstrated that leflunomide was statistically equivalent to the active comparator (methotrexate). No consistent differences were demonstrated.
- Response rates over time showed an early and sustained response in leflunomide patients in all 3 trials (MN301, US 301, MN302).

Figure 3

X-ray Data

The figure 4 below displays the change from baseline to endpoint in progression of disease as measured by the Sharp X-ray Score combining erosion and joint-space narrowing. Leflunomide was significantly superior to placebo in reducing the progression of disease as measured by the Sharp Score.

Figure 4: Change in total Sharp Score
### Functional Ability / Quality of Life

The change in patients’ functional ability, as measured by the HAQ/MHAQ Disability Index, is shown in the figure 5 below. The quality of life assessment carried out in MN301 and US301 showed that leflunomide was significantly superior to placebo. These studies also showed that leflunomide was significantly superior to SSZ and MTX in increasing the ability of subjects to perform activities of daily life. In MN302, MTX (without folic acid) achieved a greater response.

**Figure 5: Change in functional ability (HAQ/MHAQ scores)**

**Paediatrics**

Leflunomide was studied in a single multi-centre, double-blind, active-controlled trial in 94 patients (1:1 randomization) with polyarticular course juvenile rheumatoid arthritis (JRA) as defined by the American college of Rheumatology (ACR). Approximately 68% of paediatric patients receiving leflunomide, versus 89% of paediatric patients receiving the active...
comparator, improved by Week 16 (end of study) employing the JRA Definition of Improvement (DOI) ≥ responder end-point. In this trial, the loading dose and maintenance dose of leflunomide was based on 3 weight categories: < 20kg, 20 - 40kg and > 40kg. The response rate to leflunomide in paediatric patients ≤ 40kg was less robust in paediatric patients > 40kg, suggesting suboptimal dosing in smaller weight paediatric patients, as studied, resulting in less efficacious plasma concentration, despite reduced clearance of A771726 (see Section 5.2 Pharmacodynamic Properties – Paediatric Pharmacokinetics).

Paediatric Population Pharmacokinetic Analysis: The pharmacokinetics of oral leflunomide have been investigated in 73 paediatric patients with polyarticular course JRA. The results of a population pharmacokinetic analysis demonstrated that there is a similarly wide inter-subject variability in the apparent total oral clearance in paediatric patients as in adults. Body weight was strongly correlated with the apparent volume of distribution [apparent volume of distribution (L) = 5.8 x (actual body weight/40kg) 0.769] and weakly correlated with apparent total oral clearance [apparent total oral clearance (L/hr) = 0.02 x (actual body weight/40kg) 0.43] in paediatric patients with polyarticular course JRA. The half-life of A771726 decreased as body weight decreased.

The use of a loading dose may increase toxicity associated with leflunomide when used in children. The population pharmacokinetic data indicate that adult doses of leflunomide would be inappropriate in some children who would require a dose calculated from body weight. The safety and effectiveness of leflunomide in paediatric patients have not been fully evaluated. Leflunomide is not recommended for use in patients under 18 years.

Psoriatic Arthritis

The efficacy of leflunomide was demonstrated in a 6-month randomised, double-blind, placebo-controlled study in 188 Psoriatic Arthritis (PsA) patients. Adult patients with PsA were randomised to receive either leflunomide 100 mg/day for 3 days followed by 20 mg/day for the remainder of the period or placebo. In the leflunomide group, of the patients that were fully analysable (n = 186), 59% had an improvement of the Psoriatic Arthritis Treatment Response Criteria (PsARC), the primary endpoint, compared with 29.7% in the placebo group (p < 0.0001). The PsARC is a measure combining a physician global assessment, a patient global self-assessment, a joint pain/tenderness score and a joint swelling score. Improvement of the PsARC is defined as a decrease by ≥ 1 point for global assessments. An
improvement of at least 2 of the above, one of which had to be joint pain/tenderness or joint swelling score and no worsening in any of the 4 measures was required to be considered a responder.

<sup>a</sup> Negative Change Indicates Improvement
One 5-point Likert Scale (1 = Very Good; 5 = Very Poor)

In a differing analysis which excluded some patients, the Psoriasis Area and Severity Index (PASI) was assessed to reflect changes in the extent and severity of psoriasis lesions as judged by erythema, desquamation and infiltration. Leflunomide resulted in a significant improvement in PASI scores over the 24-week study relative to placebo, with a mean (± SD) improvement of 22.4% (± 51.6%) in the leflunomide group compared with a deterioration of 2.2% (± 70.4%) in the placebo group (p = 0.0030).

<sup>a</sup> p-values were calculated for difference between the treatment groups using ANOVA based on ranked percentage changes from baseline

Compared with the placebo group, a significantly greater proportion of patients in the leflunomide group experienced a ≥ 50% reduction in PASI scores (PASI 50; 18.9% vs 30.4%; p = 0.050) and ≥ 75% reduction in PASI scores (PASI 75; 7.8% vs 17.4%; p = 0.048) from baseline.

The efficacy of leflunomide in psoriatic arthritis has been assessed in a single study (n = 188) and although the results of that study were statistically significant, supporting studies
have not been performed. The efficacy of leflunomide in psoriatic arthritis patients has not been investigated beyond 6 months. The adverse events observed in the clinical study in PsA patients were comparable to the adverse events seen in the clinical trials in rheumatoid arthritis patients. Data on the safety of leflunomide in patients with PsA has been largely inferred from experience in patients with rheumatoid arthritis.

5.2 PHARMACOKINETIC PROPERTIES

Absorption
Following administration, leflunomide is rapidly and almost completely metabolised by the opening of the isoxazole ring to form the active metabolite, A771726, by first-pass metabolism in the gut wall and liver. Plasma samples taken 4 hours after the ingestion of leflunomide reveal only A771726. An absolute bioavailability study has not been performed in man. In animals, however, the bioavailability of A771726 after administration of leflunomide ranged from 76% in dog to > 90% in mouse. Following oral administration, peak levels of A771726 occurred between 6 to 12 hours after dosing. Due to the very long half-life of A771726 (~ 2 weeks), a loading dose of 100 mg leflunomide for 3 days was used in clinical studies to facilitate the rapid attainment of steady-state levels of A771726. Without a loading dose, it is estimated that attainment of steady-state plasma concentrations would require nearly 2 months of dosing. There was evidence from multiple dosing studies in patients with rheumatoid arthritis that pharmacokinetic parameters were linear over the loading dose phase used in clinical trials (i.e. 100 mg daily for 3 days) and over daily maintenance doses of 5 to 25 mg. In these studies the clinical effect was closely related to plasma concentration of A771726 and to the daily dose of leflunomide. Factors such as age, sex and body size had only a small, clinically irrelevant influence on inter-individual variability in A771726 clearance. The following plasma concentrations following both loading doses and continued clinical dosing indicate that A771726 plasma levels are dose proportional.

Table 6: Pharmacokinetic parameters for A771726 after administration of leflunomide at doses of 5, 10, 25 mg/day for 24 days to patients (n = 54) with rheumatoid arthritis (mean ± SD) (study YU204)

Relative to an oral solution, leflunomide tablets are 80% bioavailable. Food does not affect the bioavailability of leflunomide.

Distribution
In human plasma from healthy volunteers, A771726 was extensively bound (> 99.3%) to albumin. The unbound fraction of A771726 was 0.62%. Binding of A771726 was linear up to 573 μg/mL. Binding of A771726 appeared slightly reduced and more variable in plasma from patients with rheumatoid arthritis or chronic renal insufficiency such that the unbound fraction increased to 0.80% and 1.44% in these two patient groups, respectively. Consistent with extensive protein binding, A771726 had a low apparent volume of distribution (approximately
Average plasma concentration of A771726 at steady state was approximately 30 μg/mL for a maintenance dose of 20 mg/day.

**Metabolism**

Leflunomide is metabolised to one primary (A771726) and many minor metabolites. The metabolic biotransformation of A771726 is not controlled by a single enzyme and has been shown to occur in microsomal and cytosolic cellular fractions. At the present time the specific site of leflunomide metabolism is unknown. *In vivo* and *in vitro* studies suggest a role for both the GI wall and the liver in metabolism. In a study with radio-labelled \(^{(14)C}\)-leflunomide in three healthy men, no unchanged leflunomide was detected in plasma, urine or faeces. The only radio-labelled metabolite detected in plasma was A771726 and there was no preferential uptake by erythrocytes. The metabolite 4-trifluoromethylaniline (TFMA) has been detected in the plasma of animals and man but concentrations were very low compared with A771726 (ng/mL compared to μg/mL) and often below the limit of quantification. Concentrations in man were typically < 10 ng/mL whilst the highest recorded values were approximately 20 ng/mL.

**Excretion**

The active metabolite, A771726, is eliminated by further metabolism and subsequent renal excretion as well as by direct biliary excretion. In a study of radio-labelled leflunomide, excretion of radioactivity was slow, and between 89% and 94% of total radioactivity was excreted within 28 days. Approximately 43% of the total radioactivity was eliminated in the urine and 48% was eliminated in the faeces. The principal urinary metabolites were glucuronide products derived from leflunomide (mainly in 0 to 24 hour samples) and an oxanilic acid derivative of A771726. The principal faecal component was A771726. In small studies using activated charcoal (n = 1) or cholestyramine (n = 3) to facilitate drug elimination, the *in vivo* plasma half-life of A771726 was reduced from > 1 week to approximately 1 day (see **Section 4.9 Overdose**). Similar reductions in plasma half-life were observed for a series of volunteers (n = 96) enrolled in pharmacokinetic trials who were given cholestyramine. This suggests that biliary recycling is a major contributor to the long elimination half-life of A771726. Studies with both hemodialysis and CAPD (chronic ambulatory peritoneal dialysis) indicate that A771726 is not dialyzable. After independent intravenous administration of A771726, clearance averaged 31 mL/hr with an elimination half-life of 10 days. A similar clearance estimate (29 ± 17 mL/hr) was obtained from population pharmacokinetics analysis of RA patients enrolled in pivotal safety and efficacy studies.

**Paediatric Pharmacokinetics**

The pharmacokinetics of A771726 following oral administration of leflunomide have been investigated in 73 paediatric patients with polyarticular course Juvenile Rheumatoid Arthritis (JRA) who ranged in age from 3 to 17 years. The results of a population pharmacokinetic analysis of these trials have demonstrated that paediatric patients with body weights ≤ 40kg have a reduced clearance of A771726 relative to adult rheumatoid arthritis patients.

Special Populations

Gender

Gender has not been shown to cause a consistent change in the *in vivo* pharmacokinetics of leflunomide and A771726.

Age

Age has been shown to cause a change in the *in vivo* pharmacokinetics of leflunomide and A771726 (see Section 5.2 Pharmacokinetic Properties - Paediatric Pharmacokinetics above). Data in patients > 65 years are limited.

Smoking

A population based pharmacokinetic analysis of the Phase III data indicated that smokers had a 38% increase in clearance over non-smokers. However, no difference in clinical efficacy was seen between smokers and non-smokers.

Chronic Renal Impairment

In single-dose studies in patients (n = 6) with chronic renal impairment requiring either chronic ambulatory peritoneal dialysis (CAPD) or haemodialysis, neither had a significant impact on circulating levels of A771726. The free fraction of A771726 was almost doubled, but the mechanism of this increase is not known. In light of the fact that the kidneys play a role in drug elimination, and without adequate studies of leflunomide use in patients with renal impairment, caution should be used when leflunomide is administered to these patients.

Hepatic Impairment

Since the active metabolite of leflunomide, A771726, is highly protein bound and cleared via hepatic metabolism and biliary secretion, and given the risk of hepatotoxicity, leflunomide is contraindicated in patients with impairment of liver function.

5.3 PRECLINICAL SAFETY DATA

Genotoxicity

Leflunomide (A771726) was not mutagenic in bacteria (Salmonella typhimurium and Escherichia coli) or Chinese hamster ovary cells, did not cause chromosomal damage in vivo (mouse and Chinese hamster bone marrow cells) and did not induce unscheduled synthesis of DNA in vitro in mammalian cells. A minor metabolite of leflunomide, trifluoromethylaniline, was mutagenic and caused chromosomal damage in in vitro assays, but it did not cause chromosomal damage in vivo (Chinese hamster bone marrow cells) at concentrations higher than those expected in humans.

Carcinogenicity

A two-year carcinogenicity study of oral leflunomide in mice showed an increased incidence of malignant lymphoma in males given leflunomide 15 mg/kg/day [associated with plasma A771726 concentrations (AUC) similar to that expected in humans], an increase in bronchioalveolar adenomas in males given ≥ 5 mg/kg/day (A771726 AUC similar to or about 50% lower than that expected in humans) and an increase in bronchioalveolar adenomas and carcinomas in females given 1.5 mg/kg/day (A771726 AUC at least 10 - 20 times lower
than that expected in humans). The increase in the development of malignant lymphomas was probably due to the immunosuppressant effect of leflunomide. A no-effect dose or AUC for the development of lung tumours in female mice was not established, but the relevance of these findings for humans was not clear. Leflunomide showed no carcinogenicity activity in rats given oral leflunomide at doses up to 6 mg/kg/day (associated with A771726 AUC 25 - 65 times lower than that expected in humans).

The risk of malignancy, particularly lymphoproliferative disorders, is increased with the use of some immunosuppression medications. There is a potential for immunosuppression with leflunomide. No apparent increase in the incidence of malignancies and lymphoproliferative disorders was reported in the clinical trials of leflunomide, but larger and longer-term studies would be needed to determine whether there is an increased risk of malignancy or lymphoproliferative disorders with leflunomide.

6 PHARMACEUTICAL PARTICULARS

6.1 LIST OF EXCIPIENTS

Refer to section 2 and 3 – Qualitative and quantitative composition and pharmaceutical form.

6.2 INCOMPATIBILITIES

See Section 4.5-Interactions with other medicines and other forms of interactions.

6.3 SHELF LIFE

In Australia, information on the shelf life can be found on the public summary of the Australian Register of Therapeutic Goods (ARTG). The expiry date can be found on the packaging.

6.4 SPECIAL PRECAUTIONS FOR STORAGE

Store below 30°C.
Store in a dry place and keep the container tightly closed.

6.5 NATURE AND CONTENTS OF CONTAINER

10 mg tablets:
Bottle (HDPE) pack of 30 tablets: AUST R 251992.
20 mg tablets:
Bottle (HDPE) pack of 30 tablets: AUST R 251993.

6.6 SPECIAL PRECAUTIONS FOR DISPOSAL

In Australia, any unused medicine or waste material should be disposed of by taking to your local pharmacy.

6.7 PHYSICOCHEMICAL PROPERTIES

Leflunomide is a white to off white powder, practically insoluble in water and freely soluble in ethanol or acetone.
Chemical structure

Chemical Name: \( N-(4\text{-trifluoromethylphenyl})-5\text{-methylisoxazol-4-carboxamide} \)

Molecular Formula: \( C_{12}H_{9}F_{3}N_{2}O_{2} \)

Molecular Weight: 270.2

CAS number: 75706-12-6
